#### High speed modem.

© A modem is disclosed having a data transmission protocol involving lower-speed, full-duplex operation during the connect sequence with a remote modem and an automatic switch to higher-speed, half-duplex operation for data transfer. Further, the modem data transmission involves transparently changing between lower-speed, interactive operation and higher-speed operation based upon data transmission demands. The operation is controlled by a processor monitoring the contents of a transmit data buffer and providing a mode control command to the modem transmitter. The modem also adapts its speed to the quality of the telephone line by fallback or fallforward to a different speed based upon predetermined data frame retransmission criteria.

Communication of data over a telephone line is accomplished, by devices that transform a typical two-level digital computer signal into a form suitable for transmission over the telephone network For example, the two-level signal is converted into a two-frequency, sequence of signals. The conversion involves modulation at the transmitting end of the line and demodulation at the receiving end of the line. j..., Devices, ... providing these modulation/demodulation functions are referred to 

A modem is typically inserted between a data terminal, and the telephone line. A modem is, therewas a single of the fore, a two-port device having a first interface to the data terminal and a second interface to the telephone line. Control of the modulator/demodulator functions can be by a control circuit on either side of the interface to the data terminal. Control codes to modem operation may be provided from the data terminal to a control circuit via the interface. Typically, the control codes will be embedded in the serial data stream from the data terminal. A control circuit coupled to the interface receives the control commands and acts based upon them to generate control signals for the modulation/demodulation functions. Alternatively, generate the data terminal may generate the control signals for the modulation/demodulation functions.

> In order to send digital data between transmitting and receiving locations, a carrier signal is modulated based upon the data values to develop a transmit signal. Telephone lines have a limited bandwidth for signal transmission. The term "bandwidth" refers to the range of transmit signal infrequencies which can be passed without significant attenuation. The range of frequencies of a ....transmit signal, and thus the amount of bandwidth of the telephone line occupied, is dependent upon the baud rate at which data is being sent. As the speed of data transmission increases, the amount nof available bandwidth occupied also increases.

Typically, data transmission rates over telephone lines will be 300, 1200, 2400, 4800, 7200 or 9800 bits per second ("bps"). At the fastest speed of 9600 bps, essentially the entire, bandwidth is occupied by the transmit signal frequencies. For two way communication between data terminals, , half-duplex operation is typically used. This involves each modem alternately placing its transmit signal on the line. At the slower speeds, less of the total available bandwidth is occupied. The total available bandwidth can be separated into upper 6.3 and lower frequency bandwidths. By selecting separate carrier frequencies, the transmit signals will occupy separate bandwidths. This allows both transmit signals to be placed on the line at the same time for two way communication. Such communication is referred to as full-duplex operation.

The required communication speed is generally dictated by the data transmission demands of a particular application. For the transfer of files of data between data terminals, high speed data transmission is demanded to reduce the required time the telephone line is in use. For interactive communication between data terminals, full-duplex operation is desired. In some circumstances, there is the desire to both send data files and to have interactive communication. In such circumstances, the call connection often must be terminated and reestablished in order to change between operation protocols. Alternatively, time-consuming command exchanges must be made to reverse the communication roles or "turn the line around."

There is a need for higher-speed data transmission over dial-up telephone lines while retaining a full-duplex appearance at the data terminal interface. Further, there is a desire for error control along with maximum thruput and minimum echo character delay. However, economic considerations also are of concern.

Full-duplex, 9600 bps communication can be achieved using echo cancellation per V.32 standard. This solution is expensive because of the complex apparatus involved. Other approaches include fast poll, half-duplex operation using a single channel multiplexer in accordance with the V.29 standard. This operation involves line turn-around to get a minimum echo delay but does not achieve maximum thruput with error control. Alternatively, slow poll, half-duplex operation can be used but minimum echo character delay is not achieved.

The present invention economically provides the desired higher-speed data transmission and satisfies the full-duplex appearance, error control 🎵 and minimum echo character delay requirements.

In one aspect of the present invention, data transmission automatically changes from lowerspeed, full-duplex operation to higher-speed, halfduplex operation based upon data transmission de-. mands. The transmission mode transparently changes from a lower-speed, interactive mode to a higher-speed data transmission mode as data transmission demands dictate. In accordance with this aspect of the present invention, during the

handshake sequence between calling and answering modems, operation is in the lower-speed, full-duplex mode. When a large amount of data is to be sent, as in a file transfer, transition is made to the higher-speed mode.

In accordance with the present invention, a transmit data buffer is monitored. The lower-speed, full-duplex transmission mode is maintained until the buffer contains a predetermined number of characters. Operation then switches to higher-speed transmission. The transmitter is selectively operable in either a lower-speed, full-duplex mode or a higher-speed, half-duplex mode.

In another aspect of the present invention, data communication automatically changes between 15 lower-speed, full-duplex operation and higher-speed, half-duplex operation based upon data transmission demands during a communication. In accordance with this aspect, during interactive communication, operation is in the lower-speed, full-duplex mode. When a large amount of data is to be passed, operation is changed to the higher-speed, half-duplex mode.

In yet another aspect, the present invention provides for incremental changes in the speed of 25 data transmission based upon determinations of data transmission error. In accordance with this aspect, data transmission speed is adapted to the quality of the telephone line as determined by the extent of data retransmissions. Frequent data retransmission directs a fallback in speed. As the number of errors is reduced, the data transmission can fallforward in speed.

A written description setting forth the best mode presently known for carrying out the present invention, and of the manner of implementing and using it, is provided by the following detailed description of an illustrative embodiment represented in the attached drawings herein:

4. 14.

FIG. 1 is a generalized block diagram of a 40 modern in accordance with the present invention:

FIG. 2 is a functional diagram of the teles phone line interface;

FIGS. 3 and 4 combined provide a functional diagram of the modem more generally diagrammed in FIG. 1;

FIG. 5 is a diagram illustrating the connect sequence for the modern of FIGS. 1-4;

FIG. 6 is a flow chart diagram of an operational sequence of the modern of FIGS. 1-4 involvering lower-speed, full-duplex linking of the modern and subsequent higher-speed, half-duplex data transmission; and

FIG. 7 is a flow chart diagram of an operational sequence of the modern of FIGS. 1-4 involving data transmission that automatically changes between lower-speed full-duplex and higher-speed operation based upon data transmission demands during a communication and the quality of the transmissions.

Referring to FIG. 1 of the drawings, there is presented a generalized functional block diagram of apparatus for implementing the present inven-"tion. The apparatus provides for communication of "data and control commands over a telephone line to a remote site. The apparatus of FIG. 1 provides a data communication unit which generally includes a data terminal 1; an RS-232 interface 2 (port 1) and a modem 3 coupled by a hybrid circuit (port 2) to the ring (R) and tip (T) conductors of a telephone line 4. The RS-232 interface refers to a standard established by the Electronics Industries Association which defines the signal interface couplings between data terminal equipment and data communications equipment employing serial binary data interchange. As used herein, the term "data termi-"nal" refers to any external device having an RS-232 interface for providing or receiving digital data. In particular, the data terminal may be a computer, including any of the so-called "personal computers." However, the data terminal may be a printer or an information display system. Further, a parallel interface may be used and such would be fully functionally equivalent to the serial interface in the context of the present invention.

The general function of the modem 3 is, of course, to send and receive digital data. The modern accepts digital data from a data terminal and places a transmit data signal on a telephone line for communication to a remote modem coupled to a data terminal. The transmit data signal is an analog signal obtained through modulation of a carrier by a digital input. During data communication to a remote modern, the transmit data signal will contain data from the data terminal which has been encoded into the appropriate signal structure according to the applicable Bell Telephone or CCITT standards. It is to be understood that the modern also places signals on the telephone line that allow the answering modern to link with the originating modern. This involves communication of a number of parameters that allow the receiver to establish carrier detection, adjust automatic gain control circuits, establish timing synchronization, converge and adapt the equalizer to the initial line conditions, and synchronize the descrambler. Also, in the initial linking procedure, referred to in the art as the "handshake" sequence, tones will be placed on the telephone line.

In addition to accepting digital data from the data terminal for communication, i.e., TXD, and providing received digital data to the data terminal, i.e., RXD, there may be an exchange between the modern and the data terminal of various control signals such as data terminal ready (DTR), request

March 1986 Contract C The control of the send (RTS); data set ready (DSR), clear to send as (CTS) and Carrier (CXR). As will be appreciated, the control circuit func-Control of the first tions of data control and modem control may be profite assumed by the data terminal. For example, the CPU, in the data terminal may in accordance with 12:40 to appropriate software instructions provide some or a grand data buffer. If the data transmission demands of the all of the functions of data and modern control as year Alternatively, a separate circuit, peripheral, to both the data terminal and the modem, may be interconand the control circuit functions and the control circuit functions.

Javon The Further, while the data terminal 1 in the illustrative embodiment provides a local site data source. the state of a communication among be otherwise provided vided. Similarly, while communication may be to a vigorial remote modem coupled to a remote data terminal 50 serving as a remote data source and receiver. state of the contemplated. For example, and contemplated. For example, and the gremote modern may be interfaced to a ... remote data receiver in the form of an information ... display system such as a printer or character gen- 55. erator for a display device. Moreover, a remote data receiver may include data transmission capability, for communication back to the local site.

் The modemejamin Fig. 1 further includes a transmit data buffer, 28 receiving digital data from the data terminal for communication. The transmit data buffer may be physically located on either side of interface 2, Also, the buffer can be within the data terminal or in an interconnected periph-... 10 transmitter 30. The transmitter is selectively operable to transmit in either a higher-speed, half-, duplex mode or in a lower-speed, full-duplex mode. Selection of the particular mode of operation is under the direction of the processor. The transmitof the telephone line by a hybrid circuit 32. Coupled to the hybrid circuit 32 is a receiver 36. The rates and in various modes. Selection of one of the receiver outputs is made by a multiplexer 38. The serial interface circuit 40 under the direction of the processor provides received data for passage through the RS-232 interface to the data terminal.

Although the operation of an implementation of the structure generally diagrammed in FIG. 1 will be presented, a summary overview of the operation of the diagrammed modern should be mentioned to aid in understanding the description which follows. In operation, the transmit buffer holds data from the data terminal. The transmitter receives data from the transmit data buffer and places a transmit data signal on the telephone line. The transmitter is selectively operable in either a lower-speed, fullduplex mode or a higher-speed, half-duplex mode in response to a mode control command from the processor. The processor monitors the amount of data being held in the transmit data buffer and produces the mode control command to the transmitter to establish the mode of transmitter operation based upon the amount of data in the transmit data terminal are such that the transmit data buffer does not fill rapidly enough to require the higherspeed operation, the processor selects the lowerspeed, full-duplex mode of transmission. However, with such operations as file transfers or full-screen applications when data is required to be rapidly transmitted, the lower-speed mode cannot prevent the buffer from rapidly filling. When the processor determines that a predetermined number of characters is reached in the transmit data buffer, it directs the transmitter to enter the higher-speed mode of operation. When the data transmission demands decrease, the processor so determines and can direct the transmitter to enter the lower--speed mode. Also, during the connect sequence between an originating modem and an answering modem, the initial exchange of link parameters and

4

CONTRACTOR DE

other required control frame exchanges proceeds with the transmitter being directed to operate in the lower-speed; full duplex mode. When the modems have been linked and data-communication ensues, the processor directs the transmitter to operate in 55 the contents of RAM 100 during the time power is the higher-speed, half-duplex mode.

Referring next to FIG. 2, there is presented a battery circuits 102 disables RAM 100. functional' diagram of the telephone line interface in this is Turning now to FIG. 4, the higher-speed transand power supply circuits. Referring to Eigs 5, there is presented a diagram illustrating the connect sequence for the modem of Figs. 4:4. The diagram illustrates the transmitted and received signals for both an origienate modern andcan answer modern. When the originating modem initiates a call, the remote cen-  $\checkmark$ tral office sends a ring signal to the answer modem which is detected on the ring indicator RI line. The answer tone of 2225 Hz. This tone is received by the originate modern and after 455 milliseconds, .. modified by logic .0, data, referred to as scrambled the second secon Further included in FIG: 3 is a set of drivers will 15 ones. After approximately 50, to 100 milliseconds of whether the originate modern. The originate modern then identifies that the answer modem is compatible.

The modems then exchange link parameters for error control. The originate modem first sends approximately, 23 bytes of link parameter information. The answer modern receives the link parameters and if any parameters need to be changed, it sends update link parameters to the originate modem. After the update-link parameters are ex changed, the CXR and CTS lines are turned on at both modems.

When enough data accumulates in the transmit data buffer at either end to go high speed, the modems exchange control frames. Both modems then go into a squelch for a period of time, and the transmitter; of the corresponding modem begins sending data at 9600 bps. At the end of data transmission, the modems squeich and 1200 bps, full-duplex transmission is resumed and acknowledgments sent for frames received. The speed is maintained until it is time for either modem to transmit data to the other modem at higher speed. At that time, both modems squelch, and thereafter the operation continues as described above. Data transmission proceeds as required by the data transmission demands of the data terminals for the modems.

Referring next to Fig. 6 there is a flowchart of . the data transmission routine followed by the modem operating as an originate modem. At the ), start of operation, the modem performs the originate/answer connect sequence by calling and establishing a link with the answer modem in a lower-speed, full-duplex mode. There follows an and receiving of data to the data terminal equipment. If the link parameters do not agree, the modem disconnects.

When thecisending and receiving of data begins, a check isymade for data from the data: terminal. If data is being received from the data terminal, it is compressed and put into the transmit data buffer. A check is made to see whether there 1, 5 is enough data to go higher-speed, half-duplex: 🎼 👙 frames were received properly, there is considerso, the modem sets up the higher-speed, half- :: > " ation of whether a predetermined number of data duplex link and datasis transmitted in that mode, if me as a strames have been transmitted at higher-speed (e.g. there is not enough data to gothligher-speed adata as a self-case frames), all so, there is a check to determine is transmitted at lower-speed in the full-duples and swhether the transmitted data frames included any 19 日本海岸集团 (1)

At the the end of idata transmission in the meture data frame for a predetermined number of times higher-speed mode, the originate modern asks/the/pok serv(e.g. 8)-times), there is a calculation of the retransremote modern to go lower-speed, full-duplex and to send an acknowledgement. The modems establic 1/15: Idetermination is made, whether the quality of the lish the lower-speed, full-duplex link. The moderns that is data transmission indicates greatification for a fallthen checks for acknowledgment from the remote site will back in speed. If there had been retransmission of modern. If the acknowledgement does not comes to the language at least the predetermined number within a prescribed time out period, the modem initiates a recovery to establish the slower-speed of last antidibackrepeed, then the modern disconnects. If the flink: If the acknowledgment is received, the modemnae up. link is not in the lowest fallback speed, the modem to determines whether the remote modern has requested higher-speed operation. If so, the originate was reenters the transmit sequence. Emodern acknowledges the request for higher-speed to the left life the evaluation to determine whether a preand establishes the half-duplex link and sets up in https://determined/number.cof/preceding/transmitted///icit a réceive-mode. There continues to be monitoring i=i,j frames included: any retransmitted data indicates i,jfor a request to go lower-speed. When the request: (%) in that none were retransmitted frames, the routine (%): is received, the modern establishes the lowers at assignates an evaluation for qualification to fallforward to speed, full-duplex link and sends an acknowledge-workto a higher speed. If the qualification is not met, the 🐇 ment that all data frames have been received. These second framsmittisequences is reentered at the same speed, miss received data frames are decompressed and/sent/2/10/3/10/2/But.if.-the data transmission quality qualifies for a to the data terminal. The originate modern them stab too fallforward in speed, and the fink is not already in 🕬 🔆 returns to check for any data from the data-terminal what within highest speed; the modern-sets up the link for the nal: The diagrammed sequence continues until (本行 心) one step higher speed of transmission. completions of the required data communication opines a \$502. The routine in Fig. 7 illustrates the ability of the 10-16 27,259, 73 task. 

া FIG. 7 flowcharts an operational sequence কৰিবেজ প্রাচেচ্চিত্র telephone line. As indicated, the modem can either the modern involving data communication that \* 1942 \* fallback to a lower speed or fallforward to a higher automatically changes between speeds of trans-22 evisionspeed. In general, to determine the quality of the mission based upon data transmission demand at the processor of the modern constantly moniduring a communication and upon the quality of the energy tors, the number of errors in data transmission as Padata transmissions. When the modem begins transposed to the reflected by the numbers of pretransmitted data mitting; it checks for data from the data terminal angle so uframes. If the number of retransmissions is high, The data for transmission is compressed and the indicating too many errors are encountered and stored in the transmit data buffer. Next, there is \$1.2.45\(^\)\\ \line quality is poor, the modern drops down to the evaluation of whether any data is waiting for retransmission. If so and there is enough to go higher-wast ... errors in transmission is achieved. If the line quality espeed, the modern sends control frame information is in the improves and the number of errors is reduced, the to the remote modern to got higher-speed. They the the modern will automatically fallforward to the next higher-speed, half-duplex link is set up and trans- 10-50 arthigher-speed. The control is the set of mission of data begins. At the conclusion of data at the foregoing description of the present inventransmission, a control frame is sent requesting the 🐃 👙 tion has been directed to particularly preferred emremote "modem" to go into the lower-speed mode... . . . . . . bodiments for purposes of explanation and illustra-The modern then awaits reception of an acknowless tion. It will be apparent, however, to those skilled in edgement. If the acknowledgement does not come! 🖟 ss :: this cart that modifications, and changes may be within a prescribed time out period, the modem The state of the state of the state of

initiates recovery by establishing the link and reentering the transmit sequence. If the request to go lower-speed is acknowledged, the routine goes back to the beginning of the transmit sequence.

If there is no acknowledgement that all data and the second control of the second mit frame ratio. Based upon the calculated ratio, a of times, and if the modern is linked in the lowest sets up the link for one step lower in speed and

modern to adapt its speed to the quality of the next lower speed until an acceptable reduction in

made in the apparatus and operation described without departing from the scope of the invention.

#### Claims

telephone line, characterized by:

data:

data buffer, for placing a transmit signal on a way to control commandate the transmitter to select the telephone line;

either a lower-speed, full-duplex mode or a higher- and for thereafter monitoring the transmit data buffspeed, half-duplex mode in response to a mode and end providing a mode control command to the . control command; and

data being placed in the transmit data buffer and 3, 45 place 5. As modem for providing communication of producing the mode control command to the trans- in ... data over a telephone line between a local data mitter to establish the mode of transmitter operate the terminal and a remote modem, characterized by: tion based upon the data transmission demand.sign (Albertical Data at transmitter for accepting data and control

telephone line to a remote data receiver, charactered 20% a telephone line to the remote modem; ized by:

data buffer, for placing a transmit signal non a command; , , , , , , , , , , , , , , telephone line to communicate datas and control 25 frames:

said transmitter being selectively operable in either a lower-speed, full-duplex mode or achighers that a mode or a lower-speed, full-duplex mode in respeed, half-duplex mode in response to a-control speed sponse to a mode control command and providing command; and

mitter to the remote data receiver to signal-higher- a processor coupled to the transmitter and the speed operation and producing the control commands mand to the transmitter to select the higher-speed, half-duplex mode based upon the amount of idata with the processor controlling transmitter and in the transmit data buffer.

- said control circuit further provides a control frame information therebetween and thereafter conto be sent by the transmitter to the remote data. 40 trolling transmitter and receiver operation to effect receiver to signal lower-speed operation and producing the control command to the transmitter to
- 4. Apparatus for communication of data over a and the telephone line between a local data terminal and a remote modem, characterized by:
- a transmitter for accepting data and control frame information and placing a transmit signal on a telephone line;

said transmitter being selectively operable in either a lower-speed, full-duplex mode or a higherspeed, half-duplex mode in response to a control command;

a receiver for accepting a transmit signal of link control frame from a remote modem over the telephone line and providing a receive signal of control frame information;

a transmit data buffer for accepting data from

- a local data termiostics

a control circuit coupled to the transmitter to 1. Apparatus for communication of data over a supprovide control information and the mode to the receiver to manufacture to the receiver to th a transmit data buffer for accepting digital 5 obtain the receive signal of control frame informa-The second transfer of the same of

a transmitter receiving data from the transmits. So all 2 per the control circuit for providing the mode V to the conflower-speed; full-duplex mode during an exchange said transmitter being selectively operable in 10 of control frame information with a remote modem, transmitter to select the higher-speed, half-duplex a control circuit for monitoring the amount of a second based upon the data transmission demand.

2. Apparatus for communication of data over lawns at frame information and placing a transmit signal on

said transmitter being selectively operable in a transmit data buffer for holding data; www. holding eithers a lower-speed, full-duplex mode or a highera transmitter receiving data from the transmit and speed, half-duplex mode in response to a control

> a receiver for accepting a transmit signal from 2 180 2 2 2 2 a remote data communication unit over the telephone line in either a higher-speed, half-duplex 30, a receive signal;

a control circuit coupled to the transmitter, for a transmit data buffer for accepting data from

thereto;

when the second operation during a connect sequence with 3. The mode of claim 2 characterized in that the control modem to effect an exchange of control data communication with the remote modern based upon the data transmission demands by monitoring the data going to the transmit data buffer and providing a mode control command to the transmitter to select the higher-speed, half-duplex mode upon determining a predetermined number of characters in the buffer for communication and providing a mode control command to the transmitter to select the lower-speed, full-duplex mode upon determining that insufficient data is in the buffer to require higher-speed operation.

> 6. The modern of claim 5 characterized in that the processor further monitors the receive signal to determine a request by the remote modem for higher-speed operation and provides a control, command to the receiver to accept the remote modem transmit signal in a higher-speed, halfduplex mode.

- High, speed modem.
- A modem is disclosed having a data transmission protocol involving lower-speed, full-duplex operation during the connect sequence with a remote eration during the connect sequence with a remote modem and an automatic switch to higher-speed, half-duplex operation for data transfer. Further, the modem data transmission involves transparently-changing between lower-speed, interactive operation and higher-speed operation based upon data transmission demands. The operation is controlled by a processor monitoring the contents of a transmit data buffer and providing a mode control command to the modem transmitter. The modem also adapts its speed to the quality of the telephone line by fallback or fallforward to a different speed based upon-pre-

determined data frame retransmission criteria.
